# PHENYL-HETEROARYL DERIVATIVES AND METHODS OF USE THEREOF

## STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH

Not applicable

## FIELD OF THE INVENTION

This invention relates to compounds which are inhibitors of the interaction between the receptor for advanced glycation endproducts (RAGE) and its physiological ligands such as advanced glycated end products (AGEs), S100/calgranulin/EN-RAGE,  $\beta$ -amyloid, and amphoterin, for the treatment of RAGE mediated diseases.

## BACKGROUND OF THE INVENTION

The Receptor for Advanced Glycated Endproducts (RAGE) is a member of the immunoglobulin super family of cell surface molecules. The extracellular (N-terminal) domain of RAGE includes three immunoglobulin-type regions, one V (variable) type domain followed by two C-type (constant) domains (Neeper et al., J. Biol. Chem. 267:14998-15004 (1992)). A single transmembrane spanning domain and a short, highly charged cytosolic tail follow the extracellular domain. The N-terminal, extracellular domain can be isolated by proteolysis of RAGE to generate soluble RAGE (sRAGE) comprised of the V and C domains.

RAGE is expressed in most tissues, and in particular, is found in cortical neurons during embryogenesis (Hon et al. (1995)). Increased levels of RAGE are also found in aging tissues (Schleicher et al., J. Clin. Invest. 99 (3): 457-468 (1997)), and the diabetic retina, vasculature and kidney (Schmidt et al., Nature Med. 1:1002-1004 (1995)). Activation of RAGE in different tissues and organs leads to a number of pathophysiological consequences. RAGE has been implicated in a variety of conditions including: acute and chronic inflammation (Hofmann et al., Cell 97:889-901 (1999)), the development of diabetic late complications such as increased vascular permeability (Wautier et al., J. Clin. Invest. 97:238-243 (1996)), nephropathy (Teillet et al., J. Am. Soc. Nephrol. 11:1488-1497 (2000)), atherosclerosis (Vlassara et al., The Finnish Medical Society DUODECIM, Ann. Med. 28:419-426 (1996)), and retinopathy (Hammes et al., Diabetologia 42:603-607 (1999)). RAGE has also been implicated in Alzheimer's disease (Yan et al., Nature 382: 685-691 (1996)), erectile dysfunction, and in tumor invasion and metastasis (Taguchi et al., Nature 405: 354-357 (2000)).

Advanced glycation endproducts (AGEs) have been implicated in a variety of disorders including complications associated with diabetes and normal aging. Incubation of proteins or lipids with aldose sugars results in nonenzymatic glycation and oxidation of amino groups on proteins to form Amadori adducts. Over time, the adducts undergo additional rearrangements, dehydrations, and cross-linking with other proteins to form complexes known as AGEs. Factors which promote formation of AGEs include delayed protein turnover (e.g. as in amyloidoses), accumulation of macromolecules having high lysine content, and high blood glucose levels (e.g. as in diabetes) (Hori et al., J. Biol. Chem. 270: 25752-761, (1995)).

AGEs display specific and saturable binding to cell surface receptors on endothelial cells of the microvasculature, monocytes and macrophages, smooth muscle cells, mesangial cells, and neurons.

2

In addition to AGEs, other compounds can bind to, and inhibit the interaction of physiological ligands with RAGE. In normal development, RAGE interacts with amphoterin, a polypeptide which mediates neurite outgrowth in cultured embryonic neurons (Hori et al., (1995)). RAGE has also been shown to interact with EN-RAGE, a protein having substantial similarity to calgranulin (Hofmann et al. (1999)). RAGE has also been shown to interact with  $\beta$ -amyloid (Yan et al., Nature 389:689-695 (1997); Yan et al., Nature 382:685-691 (1996); Yan et al., Proc. Natl. Acad. Sci., 94:5296-5301 (1997)).

Binding of ligands such as AGEs, S100/calgranulin/EN-RAGE,  $\beta$ -amyloid, CML (N $\epsilon$ -Carboxymethyl lysine), and amphoterin to RAGE has been shown to modify expression of a variety of genes. For example, in many cell types interaction between RAGE and its ligands generates oxidative stress, which thereby results in activation of the free radical sensitive transcription factor NF- $\kappa$ B, and the activation of NF- $\kappa$ B regulated genes, such as the cytokines IL-1 $\beta$ , TNF- $\alpha$ , and the like.

In addition, several other regulatory pathways, such as those involving p21ras, MAP kinases, ERK1 and ERK2, have been shown to be activated by binding of AGEs and other ligands to RAGE. In fact, transcription of RAGE itself is regulated at least in part by NF- $\kappa$ B. Thus, an ascending, and often detrimental, spiral is fueled by a positive feedback loop initiated by ligand binding. Inhibiting binding of physiological ligands to RAGE provides for the down-regulation of the pathophysiological changes brought about by excessive concentrations of AGEs and other ligands for RAGE as described above.

Thus, there is a need for the development of compounds that inhibit the binding of physiological ligands to RAGE.

#### DETAILED DESCRIPTION OF THE INVENTION

The following definitions are meant to clarify, but not limit, the terms defined. If a particular term used herein is not specifically defined, such term should not be considered indefinite. Rather, such terms are used within their plain and ordinary meanings.

As used herein the term "alkyl" refers to a straight or branched chain hydrocarbon having one to ten carbon atoms, which may be optionally substituted as herein further described, with multiple degrees of substitution being allowed. Examples of "alkyl" as used herein include, but are not limited to, methyl, ethyl, propyl, isopropyl, isobutyl, n-butyl, tert-butyl, isopentyl, and n-pentyl.

As used throughout this specification, the number of atoms, such as carbon atoms in an alkyl group, for example, will be represented by the phrase "C<sub>x</sub>-C<sub>y</sub>, alkyl," which refers to an alkyl group, as herein defined, containing from x to y, inclusive, carbon atoms. Similar terminology will apply for other terms and ranges as well. Thus, C<sub>1</sub>-C<sub>6</sub> alkyl represents an alkyl chain having from 1 to 6 carbons as described above.

As used herein the term "alkenyl" refers to a straight or branched chain aliphatic hydrocarbon having two to ten carbon atoms and containing one or more carbon-to-carbon double bonds, which may be optionally substituted as herein further described, with multiple degrees of substitution being allowed. Examples of "alkenyl" as used herein include, but are not limited to, vinyl, and allyl.

As used herein the term "alkynyl" refers to a straight or branched chain aliphatic hydrocarbon having two to ten carbon atoms and containing one or more carbon-to-carbon triple bonds, which may be optionally substituted as herein further described, with multiple degrees of substitution being allowed. Examples of "alkynyl" as used herein include, but are not limited to, acetylene.

As used herein, the term "alkylene" refers to a straight or branched chain divalent hydrocarbon radical having from one to ten carbon atoms, which may be optionally substituted as herein further described, with multiple degrees of substitution being allowed. Examples of "alkylene" as used herein include, but are not limited to, methylene, ethylene, n-propylene, and n-butylenes.

As used herein, the term "cycloalkyl" refers to a saturated, three- to ten-membered, cyclic hydrocarbon ring, which may be optionally substituted as herein further described, with multiple degrees of substitution being allowed. Exemplary heteroatoms include nitrogen, oxygen, or sulfur atoms, including N-oxides, sulfur oxides, and sulfur dioxides. Typically, the ring is three to twelve-membered and is either fully saturated or has one or more degrees of unsaturation. Such rings may be optionally fused to one or more of another heterocyclic ring(s), cycloalkyl ring(s), aryl groups (as defined below) or heteroaryl groups (as defined below). Examples of "heterocyclic" groups as used herein include, but are not limited to, tetrahydrofuran, pyran, 1,4-dioxane, 1,3-dioxane, piperidine, pyrrolidine, morpholine, tetrahydrothiopyran, and tetrahydrothiophene.

As used herein the term "halogen" refers to fluorine, chlorine, bromine, or iodine.

As used herein the term "haloalkyl" refers to an alkyl group, as defined herein, that is substituted with at least one halogen. Examples of branched or straight chained "haloalkyl" groups as used herein include, but are not limited to, methyl, ethyl, propyl, isopropyl, n-butyl, and t-butyl substituted independently with one or more halogens, for example, fluoro, chloro, bromo, and iodo. The term "haloalkyl" should be interpreted to include groups such as —CF<sub>3</sub>, —CH<sub>2</sub>—CF<sub>3</sub>, and —CF<sub>2</sub>Cl.

As used herein, the term "direct bond", where part of a structural variable specification, refers to the direct joining of the substituents flanking (preceding and succeeding) the variable taken as a "direct bond". Where two or more consecutive variables are specified each as a "direct bond", those substituents flanking (preceding and succeeding) those two or more consecutive specified "direct bonds" are directly joined.

As used herein, the term "substituted" refers to substitution of one or more hydrogens of the designated moiety with the named substituent or substituents, multiple degrees of substitution being allowed unless otherwise stated, provided that the substitution results in a stable or chemically feasible compound. A stable compound or chemically feasible compound is one in which the chemical structure is not substantially altered when kept at a temperature from about -80° C. to about +40° C., in the absence of moisture or other chemically reactive conditions, for at least a week, or a compound which maintains its integrity long enough to be useful for therapeutic or prophylactic administration to a patient. As used herein, the phrase "substituted with one or more . . ." refers to a number of substituents that equals from one to the maximum number of substituents possible based on the number of available bonding sites, provided that the above conditions of stability and chemical feasibility are met.

As used herein, the various functional groups represented will be understood to have a point of attachment at the functional group having the hyphen or dash (-) or an asterisk (\*). In other words, in the case of —CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub>, it will be understood that the point of attachment is the CH<sub>2</sub> group at the far left.

When any variable occurs more than one time in any one constituent (e.g., R<sup>22</sup>), or multiple constituents, its definition on each occurrence is independent of its definition on every other occurrence.

In a first embodiment, the present invention provides a compound of Formula (I) or a pharmaceutically acceptable salt thereof,

The ability of compounds of Formula (I) or pharmaceutically acceptable salts thereof to inhibit the interaction of RAGE with its physiological ligands was established with representative compounds of Formula (I) or a pharmaceutically acceptable salt thereof using the assay(s) described in the Examples section below.

The invention further provides pharmaceutical compositions comprising a compound of Formula (I) or a pharmaceutically acceptable salt thereof. The term "pharmaceutical composition" is used herein to denote a composition that may be administered to a mammalian host, e.g., orally, topically, parenterally, by inhalation spray, or rectally, in unit dosage formulations containing conventional non-toxic carriers, diluents, adjuvants, vehicles and the like. The term

"parenteral" as used herein, includes subcutaneous injections, intravenous, intramuscular, intracisternal injection, or by infusion techniques.

The pharmaceutical compositions containing a compound of the invention may be in a form suitable for oral use, for example, as tablets, troches, lozenges, aqueous, or oily suspensions, dispersible powders or granules, emulsions, hard or soft capsules, or syrups or elixirs. Compositions intended for oral use may be prepared according to any known method, and such compositions may contain one or more agents selected from the group consisting of sweetening agents, flavoring agents, coloring agents, and preserving agents in order to provide pharmaceutically elegant and palatable preparations. Tablets may contain the active ingredient in admixture with non-toxic pharmaceutically-acceptable excipients which are suitable for the manufacture of tablets. These excipients may be for example, inert diluents, such as calcium carbonate, sodium carbonate, lactose, calcium phosphate or sodium phosphate; granulating and disintegrating agents, for example corn starch or alginic acid; binding agents, for example, starch, gelatin or acacia; and lubricating agents, for example magnesium stearate, stearic acid or talc. The tablets may be uncoated or they may be coated by known techniques to delay disintegration and absorption in the gastrointestinal tract and thereby provide a sustained action over a longer period. For example, a time delay material such as glyceryl monostearate or glyceryl distearate may be employed. They may also be coated by the techniques described in U.S. Pat. Nos. 4,356,108; 4,166,452; and 4,265,874, to form osmotic therapeutic tablets for controlled release.

Formulations for oral use may also be presented as hard gelatin capsules where the active ingredient is mixed with an inert solid diluent, for example, calcium carbonate, calcium phosphate or kaolin, or a soft gelatin capsules wherein the active ingredient is mixed with water or an oil medium, for example peanut oil, liquid paraffin, or olive oil.

Aqueous suspensions may contain the active compounds in admixture with excipients suitable for the manufacture of aqueous suspensions. Such excipients are suspending agents, for example sodium carboxymethylcellulose, methylcellulose, hydroxypropylmethylcellulose, sodium alginate, polyvinylpyrrolidone, gum tragacanth and gum acacia; dispersing or wetting agents may be a naturally-occurring phosphatide such as lecithin, or condensation products of an alkylene oxide with fatty acids, for example polyoxyethylene stearate, or condensation products of ethylene oxide with long chain aliphatic alcohols, for example, heptadecaethyl-eneoxycetanol, or condensation products of ethylene oxide with partial esters derived from fatty acids and a hexitol such as polyoxyethylene sorbitol monooleate, or condensation products of ethylene oxide with partial esters derived from fatty acids and hexitol anhydrides, for example polyethylene sorbitan monooleate. The aqueous suspensions may also contain one or more coloring agents, one or more flavoring agents, and one or more sweetening agents, such as sucrose or saccharin.

Oily suspensions may be formulated by suspending the active ingredient in a vegetable oil, for example arachis oil, olive oil, sesame oil or coconut oil, or in a mineral oil such as a liquid paraffin. The oily suspensions may contain a thickening agent, for example beeswax, hard paraffin or cetyl alcohol. Sweetening agents such as those set forth above, and flavoring agents may be added to provide a palatable oral preparation. These compositions may be preserved by the addition of an anti-oxidant such as ascorbic acid.

Dispersible powders and granules suitable for preparation of an aqueous suspension by the addition of water provide the

active compound in admixture with a dispersing or wetting agent, suspending agent and one or more preservatives. Suitable dispersing or wetting agents and suspending agents are exemplified by those already mentioned above. Additional excipients, for example, sweetening, flavoring, and coloring agents may also be present.

The pharmaceutical compositions of the invention may also be in the form of oil-in-water emulsions. The oily phase may be a vegetable oil, for example, olive oil or arachis oil, or a mineral oil, for example a liquid paraffin, or a mixture thereof. Suitable emulsifying agents may be naturally-occurring gums, for example gum acacia or gum tragacanth, naturally-occurring phosphatides, for example soy bean, lecithin, and esters or partial esters derived from fatty acids and hexitol anhydrides, for example sorbitan monooleate, and condensation products of said partial esters with ethylene oxide, for example polyoxyethylene sorbitan monooleate. The emulsions may also contain sweetening and flavoring agents.

Syrups and elixirs may be formulated with sweetening agents, for example glycerol, propylene glycol, sorbitol or sucrose. Such formulations may also contain a demulcent, a preservative and flavoring and coloring agents. The pharmaceutical compositions may be in the form of a sterile injectable aqueous or oleaginous suspension. This suspension may be formulated according to the known methods using suitable dispersing or wetting agents and suspending agents described above. The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally-acceptable diluent or solvent, for example as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conveniently employed as solvent or suspending medium. For this purpose, any bland fixed oil may be employed using synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

The compositions may also be in the form of suppositories for rectal administration of the compounds of the invention. These compositions can be prepared by mixing the drug with a suitable non-irritating excipient which is solid at ordinary temperatures but liquid at the rectal temperature and will thus melt in the rectum to release the drug. Such materials include cocoa butter and polyethylene glycols, for example.

For topical use, creams, ointments, jellies, solutions or suspensions, lotions, eye ointments and eye or ear drops, impregnated dressings and aerosols etc., containing the compounds of the invention are contemplated. These topical formulations may contain appropriate conventional additives such as preservatives, solvents to assist drug penetration and emollients in ointments and creams. The formulations may also contain compatible conventional carriers, such as cream or ointment bases and ethanol or oleyl alcohol for lotions. Such carriers may be present as from about 0.1% up to about 99% of the formulation. More usually they will form up to about 80% of the formulation. For the purpose of this application, topical applications shall include mouth washes and gargles.

The compounds of the present invention may also be administered in the form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles, and multilamellar vesicles. Liposomes may be formed from a variety of phospholipids, such as cholesterol, stearylamine, or phosphatidylcholines.

The compounds of the present invention may also be coupled with soluble polymers as targetable drug carriers. Such polymers can include polyvinylpyrrolidone, pyran copolymer, polyhydroxypropylmethacrylamide-phenol,

polyhydroxyethylaspartamidophenol, or polyethyleneoxide-polylysine substituted with palmitoyl residues. Furthermore, the compounds of the present invention may be coupled to a class of biodegradable polymers useful in achieving controlled release of a drug, for example, polylactic acid, polycaprolactone, polyhydroxy butyric acid, polyorthoesters, polyacetals, polydihydropyrans, polycyanoacrylates and cross-linked or amphipathic block copolymers of hydrogels.

For administration by inhalation the compounds according to the invention are conveniently delivered in the form of an aerosol spray presentation from pressurized packs or a nebulizer, with the use of a suitable propellant, e.g. dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafluoroethane, tetrafluoroethane, heptafluoropropane, carbon dioxide or other suitable gas. In the case of a pressurized aerosol the dosage unit may be determined by providing a valve to deliver a metered amount. Capsules and cartridges of e.g. gelatin for use in an inhaler or insufflator may be formulated containing a powder mix of a compound of the invention and a suitable powder base such as lactose or starch.

Compounds that antagonize the interaction of RAGE with its physiological ligands are potentially useful in treating diseases or conditions that may be responsive to the inhibiting of the RAGE receptor. The present invention provides a method of treatment comprising: administering to a subject a compound of Formula (I) or a pharmaceutically acceptable salt thereof. In an embodiment of this embodiment, the present invention provides a method for the inhibition of the interaction of RAGE with its physiological ligands. In another embodiment of this embodiment, the present invention provides a method for treating a disease state selected from the group consisting of acute and chronic inflammation including skin inflammation such as psoriasis, atopic dermatitis, inflammation associated with organ, tissue, or cell transplantation, and lung inflammation including, asthma and chronic obstructive pulmonary disease, sepsis, diabetes, diabetes related complications, renal failure, hyperlipidemic atherosclerosis associated with diabetes, neuronal cytotoxicity, restenosis, Down's syndrome, dementia associated with head trauma, amyotrophic lateral sclerosis, multiple sclerosis, amyloidosis, an autoimmune disease, wound healing, periodontal disease, neuropathy, neuronal degeneration, vascular permeability, nephropathy, atherosclerosis, retinopathy, Alzheimer's disease, erectile dysfunction, tumor invasion and/or metastasis, and osteoporosis which comprises administering to a subject a therapeutically effective amount of a compound of a compound of Formula (I) or a pharmaceutically acceptable salt thereof.

As noted above, the compounds of the present invention are useful in the treatment of the complications of diabetes. It has been shown that nonenzymatic glycoxidation of macromolecules ultimately resulting in the formation of advanced glycation endproducts (AGEs) is enhanced at sites of inflammation, in renal failure, in the presence of hyperglycemia and other conditions associated with systemic or local oxidant stress (Dyer, D., et al., *J. Clin. Invest.*, 91:2463-2469 (1993); Reddy, S., et al., *Biochem.*, 34:10872-10878 (1995); Dyer, D., et al., *J. Biol. Chem.*, 266:11654-11660 (1991); Degenhardt, T., et al., *Cell Mol. Biol.*, 44:1139-1145 (1998)). Accumulation of AGEs in the vasculature can occur focally, as in the joint amyloid composed of AGE- $\beta$ 2-microglobulin found in patients with dialysis-related amyloidosis (Miyata, T., et al., *J. Clin. Invest.*, 92:1243-1252 (1993); Miyata, T., et al., *J. Clin. Invest.*, 98:1088-1094 (1996)), or generally, as exemplified by the vasculature and tissues of patients with diabetes (Schmidt, A-M., et al., *Nature Med.*, 1:1002-1004 (1995)).

The progressive accumulation of AGEs over time in patients with diabetes suggests that endogenous clearance mechanisms are not able to function effectively at sites of AGE deposition. Such accumulated AGEs have the capacity to alter cellular properties by a number of mechanisms. Although RAGE is expressed at low levels in normal tissues and vasculature, in an environment where the receptor's ligands accumulate, it has been shown that RAGE becomes upregulated (Li, J. et al., *J. Biol. Chem.*, 272:16498-16506 (1997); Li, J., et al., *J. Biol. Chem.*, 273:30870-30878 (1998); Tanaka, N., et al., *J. Biol. Chem.*, 275:25781-25790 (2000)). RAGE expression is increased in endothelium, smooth muscle cells and infiltrating mononuclear phagocytes in diabetic vasculature. Also, studies in cell culture have demonstrated that AGE-RAGE interaction caused changes in cellular properties important in vascular homeostasis.

Also as noted above, the compounds of the present invention are useful in treating amyloidoses and/or Alzheimer's Disease. RAGE appears to be a cell surface receptor which binds  $\beta$ -sheet fibrillar material regardless of the composition of the subunits (amyloid- $\beta$  peptide, A $\beta$ , amylin, serum amyloid A, prion-derived peptide) (Yan, S.-D., et al., *Nature*, 382:685-691 (1996); Yan, S.-D., et al., *Nat. Med.*, 6:643-651 (2000)). Deposition of amyloid has been shown to result in enhanced expression of RAGE. For example, in the brains of patients with Alzheimer's disease (AD), RAGE expression increases in neurons and glia (Yan, S.-D., et al., *Nature* 382:685-691 (1996)). The consequences of A $\beta$  interaction with RAGE appear to be quite different on neurons versus microglia. Whereas microglia become activated as a consequence of A $\beta$ -RAGE interaction, as reflected by increased motility and expression of cytokines, early RAGE-mediated neuronal activation is superceded by cytotoxicity at later times. Further evidence of a role for RAGE in cellular interactions of A $\beta$  concerns inhibition of A $\beta$ -induced cerebral vasoconstriction and transfer of the peptide across the blood-brain barrier to brain parenchyma when the receptor was blocked (Kumar, S., et al., *Neurosci. Program*, p141 (2000)). Inhibition of RAGE-amyloid interaction has been shown to decrease expression of cellular RAGE and cell stress markers (as well as NF- $\kappa$ B activation), and diminish amyloid deposition (Yan, S.-D., et al., *Nat. Med.*, 6:643-651 (2000)) suggesting a role for RAGE-amyloid interaction in both perturbation of cellular properties in an environment enriched for amyloid (even at early stages) as well as in amyloid accumulation.

In other studies using a mouse model of Alzheimer's Disease, it has been shown that RAGE antagonists can reverse the formation of plaques and the loss of cognition. In U.S. Patent Publication No. US 2005/0026811, small molecule RAGE antagonists were used to inhibit the progression of A $\beta$  deposition and reduced the volume of preexisting plaques in Alzheimer's Disease mice (US 2005/0026811 at ¶¶581-586). Furthermore, treatment with such small molecule RAGE antagonists improved cognition in these Alzheimer's Disease mouse models (US 2005/0026811 at ¶¶587-590). Thus, in a mouse model of Alzheimer's Disease, those mice who had developed A $\beta$  plaques and cognitive loss and were treated with small molecule RAGE antagonists exhibited a reduction in plaque volume and an improvement in cognitive performance as compared to those Alzheimer's Disease mice who were not treated with the small molecule RAGE antagonists, showing that the RAGE antagonist compounds may delay or slow loss of cognitive performance, or may improve cognitive performance of a subject suffering from dementia of Alzheimer's type.

Also, it had been shown in both cellular assays and in animal studies that RAGE mediates the transcytosis of circu-

lating A $\beta$  across the blood-brain barrier (BBB). Such increased transcytosis of A $\beta$  results in neuronal oxidant stress and sustained reductions in cerebral blood flow. The effects of RAGE can be inhibited by a RAGE modulator (e.g., anti-RAGE antibody or sRAGE) (see e.g., Mackic et al., *J. Clin. Invest.*, 102:734-743 (1998); see also Kumar et al., *Neurosci. Program*, p 141 (2000)). These finding were confirmed by additional studies (see e.g., U.S. Pat. No. 6,825,164 at col. 17, line 48 to col. 18, line 43; Deane et al., *Nature Medicine*, 9:907-913 (2003)). Reduced cerebral perfusion can promote ischemic lesions which can act synergistically with A $\beta$  to exacerbate dementia. Also, insufficient cerebral blood flow may alter A $\beta$  trafficking across the blood brain barrier thereby reducing A $\beta$  clearance and promoting accumulation of A $\beta$  in brain (see Girouard and Iadecola, *J. Appl. Physiol.*, 100, 328-335 (2006) at page 332). Thus, the increase in cerebral blood flow promoted by RAGE antagonists may reduce the symptoms or delay onset of development of Alzheimer's Disease, or both. For example, RAGE antagonists may delay or slow loss of cognitive performance, or may improve cognitive performance of a subject suffering from dementia of Alzheimer's type, or both.

As noted above, the compounds of the present invention are useful in treating inflammation. For example, S100/calgranulins have been shown to comprise a family of closely related calcium-binding polypeptides characterized by two EF-hand regions linked by a connecting peptide (Schafer, B. et al., *TISS*, 21:134-140 (1996); Zimmer, D., et al., *Brain Res. Bull.*, 37:417-429 (1995); Rammes, A., et al., *J. Biol. Chem.*, 272:9496-9502 (1997); Luger, N., et al., *Eur. J. Clin. Invest.*, 25:659-664 (1995)). Although they lack signal peptides, it has long been known that S100/calgranulins gain access to the extracellular space, especially at sites of chronic immune/inflammatory responses, as in cystic fibrosis and rheumatoid arthritis. RAGE is a receptor for many members of the S100/calgranulin family, mediating their proinflammatory effects on cells such as lymphocytes and mononuclear phagocytes. Also, studies on delayed-type hypersensitivity response, colitis in IL-10 null mice, collagen-induced arthritis, and experimental autoimmune encephalitis models suggest that RAGE-ligand interaction (presumably with S100/calgranulins) has a proximal role in the inflammatory cascade as implicated in the inflammatory diseases such as but not limited to rheumatoid arthritis and multiple sclerosis.

RAGE is also implicated in inflammatory diseases of the skin such as but not limited to atopic dermatitis, eczema, and psoriasis. Psoriasis in particular is characterized by inflamed itchy lesions. Psoriasis may be accompanied by arthropathic symptoms that are similar to those in seen in rheumatoid arthritis. There is considerable evidence that psoriasis is a polygenic autoimmune disorder. Psoriatic lesions are rich in cytokines, in particular IL-1 and IL-8, both potent proinflammatory mediators. IL-8 in particular is a chemotactic factor for neutrophils; neutrophils are also known to synthesize and secrete S100 proteins, one of the ligands for RAGE which is implicated in propagation of the immune and inflammatory response. Psoriasin, (S100A7) a new member of the S100 gene family, is a secreted protein isolated from psoriatic skin. Semprini et al. (*Hum. Genet.* 2002 October, 111(4-5), 310-3) have shown a linkage of psoriasis genetic susceptibility to distinct overexpression of S100 proteins in skin. Therefore, a modulator of RAGE would be expected to regulate the immune response in psoriasis.

As noted above, the compounds of the present invention are useful in treating tumor and tumor metastasis. For example, amphotericin is a high mobility group I nonhistone chromosomal DNA binding protein (Rauvala, H., et al., *J.*

Biol. Chem., 262:16625-16635 (1987); Parkikinen, J., et al., J. Biol. Chem. 268:19726-19738 (1993)) which has been shown to interact with RAGE. It has been shown that amphoterin promotes neurite outgrowth, as well as serving as a surface for assembly of protease complexes in the fibrinolytic system (also known to contribute to cell mobility). In addition, a local tumor growth inhibitory effect of blocking RAGE has been observed in a primary tumor model (C6 glioma), the Lewis lung metastasis model (Taguchi, A., et al., Nature 405:354-360 (2000)), and spontaneously arising papillomas in mice expressing the v-Ha-ras transgene (Leder, A., et al., Proc. Natl. Acad. Sci., 87:9178-9182 (1990)).

Airway inflammation is important in the pathogenesis of asthma. Such inflammation may give rise to significant exacerbations and increases in asthma severity, as well as to be a major factor in a decline in asthmatic status. In severe exacerbations of asthma there is an intense, mechanistically heterogeneous inflammatory response involving neutrophil and eosinophil accumulation and activation. Neutrophils are a significant source of S100 proteins, key ligands for RAGE implicated in the propagation of the immune response and inflammation. Therefore, modulators of RAGE would be expected to possess therapeutic value in the treatment of asthma. Further, the propagation step in the immune response in the lung driven by S100-RAGE interaction would be expected to lead to the activation and/or recruitment of inflammatory cells, such as neutrophils, which in chronic obstructive pulmonary diseases such as emphysema, are significant sources of damaging proteases. Therefore, a RAGE modulator would be expected possess potential in the treatment of chronic obstructive pulmonary diseases.

As used herein, the phrase "therapeutically effective amount" shall mean that amount of a drug or pharmaceutical agent that will elicit the therapeutic response of a subject that is being sought.

The residue was dissolved in ethyl acetate (200 mL), washed with saturated  $\text{NaHCO}_3$  (3×100 mL), brine (100 mL), dried ( $\text{Na}_2\text{SO}_4$ ) filtered and concentrated under reduced pressure. The residue was purified on a 330 g  $\text{SiO}_2$  cartridge eluting with 0-10% ethyl acetate in hexanes to afford 3-butyl-6-chloro-4-(4-cyclohexyloxy-phenyl)-pyridazine.

To a stirred solution of 4-hydroxy-piperidine-1-carboxylic acid tert-butyl ester (94.2 mmol, 18.97 g) in THF (100 mL) at room temperature was added potassium tert-butoxide (87.0 mmol, 9.76 g) and continued stirring for 15 min. The reaction mixture was cooled to 0° C. using an ice bath. To this was added a solution of 3-butyl-6-chloro-4-(4-cyclohexyloxy-phenyl)-pyridazine (72.5 mmol, 25.0 g) in THF (100 mL). The reaction mixture was allowed to slowly attain room temperature while stirring overnight. The reaction was poured into a mixture of water (300 mL) and ethyl acetate (300 mL). The mixture was shaken and separated. The aqueous layer was extracted with ethyl acetate (2×100 mL). The combined organic layer was washed with brine (50 mL), dried ( $\text{Na}_2\text{SO}_4$ ), filtered and concentrated under reduced pressure. The residue was purified on 330 g  $\text{SiO}_2$  cartridge using an ethyl acetate/hexanes gradient to provide 4-[6-butyl-5-(4-cyclohexyloxy-phenyl)-pyridazin-3-yloxy]-piperidine-1-carboxylic acid tert-butyl ester.

To a solution of the tert-butyl ester (39.2 mmol, 20.0 g) in DCM (50 mL) was added 4 N HCl in dioxane (50 mL), and the reaction was stirred for 45 min. The solvents were removed in vacuo and the residue was triturated with anhydrous ethyl ether (50 mL) and filtered and washed the cake with ethyl ether (50 mL). The off-white solid was dried overnight at 50° C. under high vacuum to provide 3-butyl-4-(4-cyclohexyloxy-phenyl)-6-(piperidin-4-yloxy)-pyridazine dihydrochloride.

To a solution of 3-butyl-4-(4-cyclohexyloxy-phenyl)-6-(piperidin-4-yloxy)-pyridazine dihydrochloride (0.2 mmol, 82 mg) in DCM (2 mL) was added formaldehyde solution in water (37%, 2 mmol, 0.2 mL), and 1 drop of acetic acid. Then sodium triacetoxyborohydride (2 mmol, 424 mg) was added, and the mixture was stirred at room temperature for 0.5 hour then condensed. It was then diluted with water/EtOAc and neutralized with  $\text{NaHCO}_3$  powder. The organic layers were combined and dried over  $\text{Na}_2\text{SO}_4$ . The solvent was removed in vacuo and the residue was purified by silica gel chromatography (DCM to DCM+10% 2N ammonia in MeOH) to provide 3-butyl-4-(4-cyclohexyloxy-phenyl)-6-(1-methyl-piperidin-4-yloxy)-pyridazine. The solid was dissolved in 1 mL DCM, 2N HCl in ether (1 mL) was added, kept at room temperature for 10 min, condensed, triturated with hexanes to provide the title compound (79 mg). ## Binding Assay

The following assay method may be used to identify compounds of Formula (I) or pharmaceutically acceptable salts

## 157

thereof which are useful as inhibitors of binding of physiological RAGE ligands, such as S100b and  $\beta$ -amyloid, to RAGE.

S100b,  $\beta$ -amyloid, or CML (500 ng/100  $\mu$ L/well) in 100 mM sodium bicarbonate/sodium carbonate buffer (pH 9.8) is loaded onto the wells of a NUNC Maxisorp flat bottom 96-well microtitre plate. The plate is incubated at 4° C. overnight. The wells are aspirated and treated with 50 mM imidazole buffer saline (pH 7.2) (with 5 mM  $\text{CaCl}_2/\text{MgCl}_2$ ) containing 1% bovine serum albumin (BSA) (300  $\mu$ L/well) for 1 h at RT. The wells are aspirated.

Test compounds are dissolved in nanopure water (concentration: 10-100  $\mu$ M). DMSO may be used as co-solvent. 25  $\mu$ L of test compound solution in 4% DMSO is added, along with 75  $\mu$ L sRAGE (6 nM FAC) to each well and samples are incubated for 1 h at 37° C. The wells are washed several times with 155 mM NaCl pH 7.2 buffer saline and are soaked for several seconds between each wash.

Non-radioactive detection is performed by adding:

10  $\mu$ L Biotinylated goat F(ab')<sub>2</sub> Anti-mouse IgG. (8.0 $\times$  10<sup>-4</sup> mg/mL, FAC), 5  $\mu$ L Alk-phos-Streptavidin (3 $\times$ 10<sup>-3</sup> mg/mL FAC), 0.42  $\mu$ L per 5 mL Monoclonal antibody for sRAGE (FAC 6.0 $\times$ 10<sup>-3</sup> mg/mL) to 5 mL 50 mM imidazole buffer saline (pH 7.2) containing 0.2% bovine serum albumin and 5 mM  $\text{CaCl}_2$ . The mixture is incubated for 30 minutes at RT.

100  $\mu$ L of complex is added to each well and incubation is allowed to proceed at rt for 1 h. Wells are washed several times with wash buffer and soaked several seconds between each wash. 100  $\mu$ L 1 mg/mL (pNPP) in 1 M diethanolamine (pH adjusted to 9.8 with HCl) is added. Color is allowed to develop in the dark for 30 min to 1 h at rt. The reaction is quenched with 10  $\mu$ L of stop solution (0.5-1.0 N NaOH in 50% ethanol) and the absorbance is measured spectrophotometrically with a microplate reader at 405 nm.

The Examples 1-115 (hydrochloride salt form) were tested according to the assay method described above, employing S100b or  $\beta$ -amyloid as the RAGE ligand, and were found to possess IC<sub>50</sub> concentrations shown below. The IC<sub>50</sub> ( $\mu$ M) value in the ELISA assay represents the concentration of compound at which 50% signal has been inhibited.

## Functional Assay

Previously the literature has cited that THP-1 cells in response to RAGE ligands secrete TNF alpha (Yeh C-H, et al. Diabetes. Vol. 50, June 2001, pp. 1495-1504). The following assay method may be used to identify compounds of Formula (I) or pharmaceutically acceptable salts thereof which are useful as antagonists of RAGE signaling.

The myeloid cell line, THP-1 (ATCC # TIB-202), may be cultured in RPMI-1640 media (ATCC, Cat #30-2001) supplemented with fetal bovine serum to a final concentration of 10% by volume and Penicillin-Streptomycin (Gibco, Cat #0.15140-122). Alternatively, media may be formulated using RPMI 1640 (Bio-Whitaker #12-702F) supplemented with 2 mM L-glutamine (Gibco #12381-018) adjusted to contain 1.5 g/L sodium bicarbonate (Gibco #25080-094), 4.5 g/L glucose, 10 mM HEPES (Cellgro #25-060-L1) and 1.0 mM sodium pyruvate (Gibco #11360-070) and supplemented with 0.05 mM 2-mercaptoethanol, 90% fetal bovine serum, 10% per ATCC instructions. During culture, the culture cells are maintained at a density between  $5 \times 10^4$  and  $1 \times 10^6$  viable cells/mL. The cell doubling time is approximately 20 hours and the cells should be passed every 3-4 days.

THP1 cells are first harvested by centrifugation and then washed 1 time with RPMI containing Pen Strep without serum. The cells are resuspended to a final concentration of between  $5 \times 10^5$  and  $1 \times 10^6$  cells/mL in RPMI without serum. The cells are dispensed into a 96-well tissue culture plate (Corning, CSL3599) at 50,000-100,000 cells per well in 100  $\mu$ L of RPMI. Following plating of cells, compounds are dispensed and serially diluted using DMSO. DMSO and compound concentrations are adjusted with RPMI to give a final concentration of DMSO no greater than 0.5% in the cell culture. Typically, compounds are diluted into 50  $\mu$ L of RPMI prior to addition to culture. Compounds are incubated with the cells for 30 minutes at 37° C. and 5% CO<sub>2</sub> to equilibrate the compound in culture. After the 30 minute preincubation, the cells are stimulated with bovine S100b at a final concentration of 100  $\mu$ g/mL. This material is prepared by dissolving bovine S100b (Calbiochem, #559290) in RPMI to a final concentration of 0.4 mg/mL. Assays may be run in the presence of a RAGE fusion protein or with sRAGE as a positive control or a human IgG (Sigma #14506) as a negative control.

The amount of TNF-alpha secreted by the THP-1 cells was measured 24 hours after the addition of the stimulant proteins to the cell culture using a commercially available ELISA kit (R&D Systems, Minneapolis, Minn. # DY210). All reagents and standards are prepared as directed by the manufacturer.

Then, 100  $\mu$ L of standards, media controls or media samples are added to the appropriate ELISA well. The plate is incubated at room temperature (22-25° C.) for 2 hours. The plate is then aspirated and washed with 400  $\mu$ L of wash buffer (PBS+0.1% Tween-20) and repeated three more times for a total of four washes. Next, 100  $\mu$ L of TNF-alpha detection conjugate is added to each ELISA well and allowed to incubate at room temperature for one hour. The plate is then aspirated and washed with 400  $\mu$ L of wash buffer and repeated three more times for a total of four washes. Next, 100  $\mu$ L of a preparation of streptavidin conjugated to horseradish peroxidase is added to each well and allowed to incubate for 20 minutes. The plate is then aspirated and washed with 400  $\mu$ L of wash buffer and repeated three more times for a total of four washes. Color development is initiated by the addition of 100  $\mu$ L of TMB Substrate Solution (Sigma, T0440-1L) and incubated for 10-20 minutes. The color development is stopped by addition of 100  $\mu$ L of 1M phosphoric acid. The plate is read at 450 nm within 30 minutes. With S100b stimulation, 125-250 pg/mL are seen above background.

Example 14 had an EC50 for TNF expression of 1.26  $\mu$ M. Thus, the cell based assay demonstrated a correlation with the binding assay data for Example 14 which had an IC50 of 0.82  $\mu$ M in the binding assay.
